## CSC411 Tutorial #5 Neural Networks

#### Oct, 2017 Shengyang Sun ssy@cs.toronto.edu

\*Based on the lectures given by Professor Sanja Fidler and the prev. tutorial by Boris Ivanovic, Yujia Li.

# High-Level Overview

- A Neural Network is a function!
- It (generally) comprised of:
  - Neurons which pass input values through functions and output the result
  - Weights which carry values between neurons
- We group neurons into **layers**. There are 3 main types of layers:
  - Input Layer
  - Hidden Layer(s)
  - Output Layer

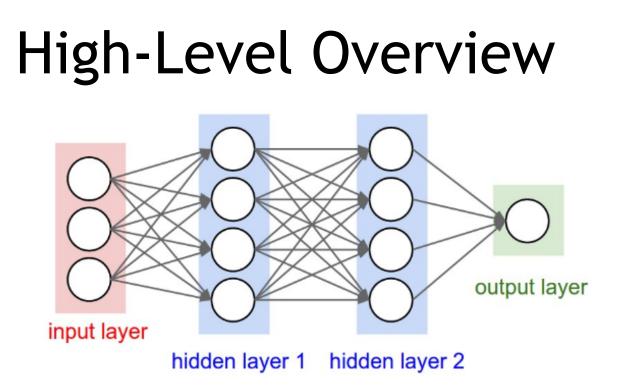

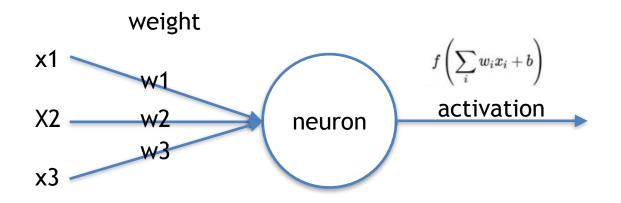

Figure: A 3-layer neural net with 3 input units, 4 hidden units in the first and second hidden layer and 1 output unit

- Naming conventions; a N-layer neural network:
  - ▶ *N* − 1 layers of hidden units
  - One output layer

#### Neuron Breakdown

### Neuron Breakdown

## **Activation Functions**

Most commonly used activation functions:

• Sigmoid: 
$$\sigma(z) = \frac{1}{1 + \exp(-z)}$$

- Tanh:  $tanh(z) = \frac{exp(z) exp(-z)}{exp(z) + exp(-z)}$
- ReLU (Rectified Linear Unit):  $\operatorname{ReLU}(z) = \max(0, z)$

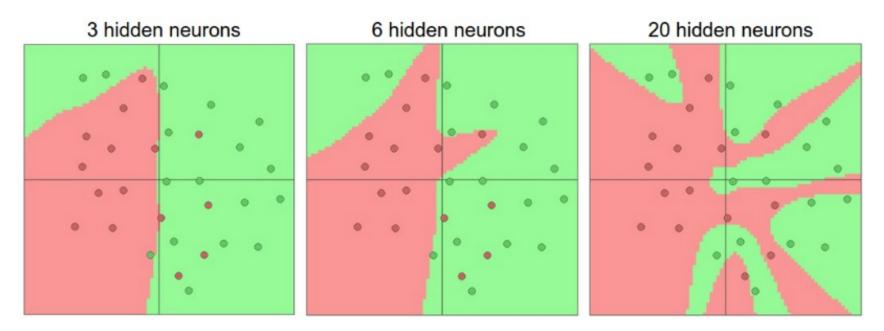

Most popular recently for deep learning

# **Representation Power**

 Neural network with at least one hidden layer is a universal approximator (can represent any function).

Proof in: Approximation by Superpositions of Sigmoidal Function, Cybenko, paper

 The capacity of the network increases with more hidden units and more hidden layers

# What does this mean?

• Neural Networks are **POWERFUL**, it's exactly why with recent computing power there was a renewed interest in them.

#### BUT

- "With great power comes great overfitting." – Boris Ivanovic, 2016
- Last slide, "20 hidden neurons" is an example.

## How to mitigate this?

• Stay Tuned!

• First, how do we even use or train neural networks?

#### Training Neural Networks (Key Idea)

• Find weights:

$$\mathbf{w}^* = \operatorname*{argmin}_{\mathbf{w}} \sum_{n=1}^{N} \operatorname{loss}(\mathbf{o}^{(n)}, \mathbf{t}^{(n)})$$

where  $\mathbf{o} = f(\mathbf{x}; \mathbf{w})$  is the output of a neural network

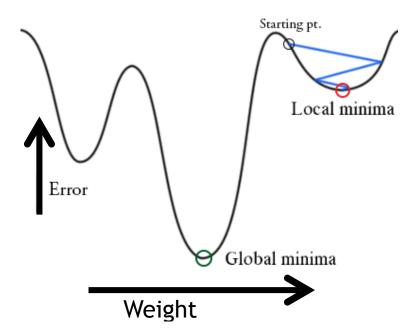

- Define a loss function, eg:
  - Squared loss:  $\sum_{k} \frac{1}{2} (o_k^{(n)} t_k^{(n)})^2$  (Regression)
  - Cross-entropy loss:  $-\sum_{k} t_{k}^{(n)} \log o_{k}^{(n)}$  (Classification)
- Gradient descent:

$$\mathbf{w}^{t+1} = \mathbf{w}^t - \eta \frac{\partial E}{\partial \mathbf{w}^t}$$

where  $\eta$  is the learning rate (and E is error/loss)

### Training Compared to Other Models

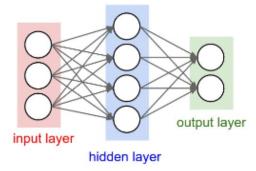

- Training Neural Networks is a NON-CONVEX OPTIMIZATION PROBLEM.
- This means we can run into many local optima during training.

Training Neural Networks (Implementation)

- We need to first perform a forward pass
- Then, we update weights with a backward pass

## Forward Pass (AKA "Inference")

Output of the network can be written as:

$$egin{array}{rll} h_{j}({f x}) &=& f(v_{j0}+\sum_{i=1}^{D}x_{i}v_{ji}) \ o_{k}({f x}) &=& g(w_{k0}+\sum_{j=1}^{J}h_{j}({f x})w_{kj}) \end{array}$$

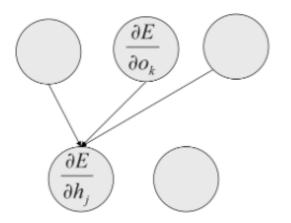

(j indexing hidden units, k indexing the output units, D number of inputs)

• Activation functions f, g: sigmoid/logistic, tanh, or rectified linear (ReLU)

$$\sigma(z) = \frac{1}{1 + \exp(-z)}, \quad \tanh(z) = \frac{\exp(z) - \exp(-z)}{\exp(z) + \exp(-z)}, \quad \operatorname{ReLU}(z) = \max(0, z)$$

# Backward Pass (AKA "Backprop.")

 Compute error derivatives in each hidden layer from error derivatives in layer above. [assign blame for error at k to each unit j according to its influence on k (depends on w<sub>kj</sub>)]

 Use error derivatives w.r.t. activities to get error derivatives w.r.t. the weights.

## Learning Weights during Backprop

- Do exactly what we've been doing!
- Take the derivative of the error/cost/loss function w.r.t. the weights and minimize via gradient descent!

Gradient descent:

$$\mathbf{w}^{t+1} = \mathbf{w}^t - \eta \frac{\partial E}{\partial \mathbf{w}^t}$$

where  $\eta$  is the learning rate (and E is error/loss)

### **Useful Derivatives**

name	function	derivative
Sigmoid	$\sigma(z) = rac{1}{1+\exp(-z)}$	$\sigma(z) \cdot (1 - \sigma(z))$
Tanh	$ anh(z) = rac{\exp(z) - \exp(-z)}{\exp(z) + \exp(-z)}$	$1/\cosh^2(z)$
ReLU	$\operatorname{ReLU}(z) = \max(0, z)$	$egin{cases} 1, &  ext{if } z > 0 \ 0, &  ext{if } z \leq 0 \end{cases}$

# Preventing Overfitting

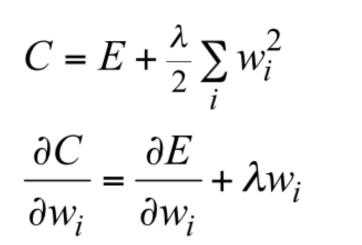

Standard ways to limit the capacity of a neural net:

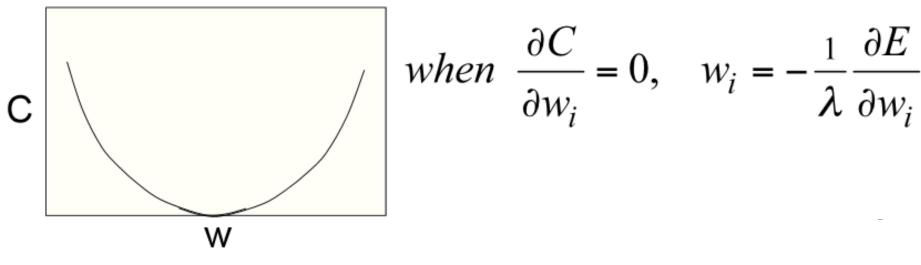

- Limit the number of hidden units.
- Limit the size of the weights. Weight decay
- Stop the learning before it has time to overfit Early stop

# Limiting the Size of the Weights

Weight-decay involves adding an extra term to the cost function that penalizes the squared weights.

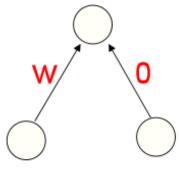

> Keeps weights small unless they have big error derivatives.

# The Effects of Weight-Decay

- It prevents the network from using weights that it does not need
  - This can often improve generalization a lot.
  - It helps to stop it from fitting the sampling error.
  - It makes a smoother model in which the output changes more slowly as the input changes.
- But, if the network has two very similar inputs it prefers to put half the weight on each rather than all the weight on one → other form of weight decay?

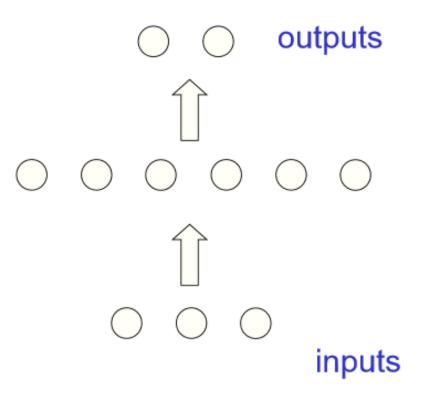

# Early Stopping

- If we have lots of data and a big model, its very expensive to keep re-training it with different amounts of weight decay
- It is much cheaper to start with very small weights and let them grow until the performance on the validation set starts getting worse
- The capacity of the model is limited because the weights have not had time to grow big.

# Why Early Stopping Works

- When the weights are very small, every hidden unit is in its linear range.
  - So a net with a large layer of hidden units is linear.
  - It has no more capacity than a linear net in which the inputs are directly connected to the outputs!
- As the weights grow, the hidden units start using their non-linear ranges so the capacity grows.
