#### ABSTRACT

Signaling pathways transmit information through protein interaction networks that are dynamically regulated by complex extracellular cues. We developed an automated highthroughput technology we call LUMIER to analyze dynamic protein-protein interaction networks in mammalian cells. LUMIER was used to systematically analyze the interaction of 518 proteins with components of the TGF $\beta$  pathway and identified 901 interactions from 11,914 tests. Analysis of the Smad network module in the presence and absence of TGF $\beta$  signaling revealed a dynamic network in which numerous interactions were lost, while others were gained. The TGFβ LUMIER network was analyzed using the BTSVQ algorithm, which incorporates self-organizing maps and k-means clustering. This identified a group of proteins that showed similar interactions with the TGF<sup>β</sup> pathway and included components of both the p21 activated kinase (PAK) and polarity pathways. Moreover, TGF $\beta$  receptors made numerous connections with these two networks that otherwise display only sparse connectivity. High-throughput mapping of protein interactions in mammalian cells thus demonstrates a link between the TGF<sup>β</sup> pathway and both the PAK and polarity subnetworks, that yields a large interconnected network involved in cell motility and polarity.

Dynamic protein-protein interactions (PPIs) are key for cell signaling and dictate timing and intensity of network outputs. However, systematic mapping of PPI networks have thus far focussed on static analyses in *S. cerevisiae*, *D. melanogaster* and *C. elegans* (*1*-6). Therefore, to begin building an understanding of how signaling networks convey information in vertebrates we developed a high-throughput (HTP) strategy to systematically map PPIs in mammalian cells. This strategy, which we call LUMIER, for <u>LU</u>minescence-based <u>Mammalian IntER</u>actome mapping (Fig. 1A), employs Renilla luciferase enzyme (RL) fused to proteins of interest. RL-tagged proteins are then coexpressed with individual Flag-tagged partners in mammalian cells and interaction determined by performing an RL enzymatic assay on anti-Flag immunoprecipitates.

**Validation of LUMIER.** As a model for a systematic study of mammalian cell signaling, we focussed on the TGF $\beta$  superfamily of extracellular morphogens, which regulate a plethora of biological processes in metazoans (7-11). The superfamily includes the TGF $\beta$ s, bone morphogenetic proteins (BMPs) and activins, which signal through heteromeric complexes of type II and type I transmembrane ser/thr kinase receptors. The receptor complex is activated when the type II receptor kinase transphosphorylates the type I receptor (Fig. 1B), which stimulates binding and phosphorylation of receptor-regulated Smads (R-Smads) by the type I receptor. R-Smad2 and R-Smad3 function in TGF $\beta$  signaling, whereas the BMPs through different type I receptors (ALK2, ALK3 and ALK6) activate R-Smad1, R-Smad5 and R-Smad8. Phosphorylated R-Smads dissociate from the receptor, form a complex with the common mediator Smad, Smad4, and this

complex then accumulates in the nucleus where it regulates transcription by interacting with DNA binding proteins (12).

The Smad pathway provides an example of how post-translational modifications (PTMs) regulate the dynamics of PPI networks to control signal transduction (13, 14). Therefore, we used this pathway to determine whether LUMIER could map PTM-dependent interactions (Fig. 1). For this, we fused RL to Smad4 (Smad4-RL) and co-expressed it with Flag-Smad2 or the TGF $\beta$  receptor phosphorylation site mutant, Flag-Smad2(2SA), which does not bind Smad4. In the absence of signaling, little if any Smad4-RL was found associated with Smad2 (Fig. 1C), whereas TGFβ signaling induced strong association with WT Smad2 that was revealed by high levels of RL activity in the immune complexes (15). In contrast, no Smad4-RL was detected in Smad2(2SA) immunoprecipitates. We also examined signal-specific interactions using the BMP pathway and observed increased Smad4-RL bound to Flag-Smad1 but not Smad2, upon activation of BMP signaling (Fig. 1D). LUMIER also recapitulated constitutive interactions such as that between Smad4 and the co-repressor SnoN (Fig. 1E). Furthermore, it detected the transient interaction between Smad2 and constitutively active RL-tagged T $\beta$ RI (Fig. 1F) that is difficult to detect by traditional means. Thus, LUMIER recapitulates pathway-specific PTM-dependent PPIs, constitutive protein interactions and interactions involving transmembrane receptors. The latter is noteworthy as transmembrane receptors are critical focal points in signaling networks, are important drug targets and have been difficult to study using HTP approaches (16).

**High-throughput LUMIER.** LUMIER demonstrated very high sensitivity and faithfully recapitulated dynamic interactions in the TGF<sup>β</sup> pathway, suggesting that it might be amenable for mapping PPI networks in mammalian cells. For proof of principle, we optimized LUMIER in a 96-well format and performed a pilot-screen of Smad4-RL against 30 different Flag-tagged cDNAs in the presence or absence of TGFβ signaling (Fig. 2A). This revealed low background and strong, signal-dependent interactions between Smad4-RL and either Flag-Smad2 or Flag-Smad3, as well as the interaction of Smad4-RL with Flag-Ski, as previously reported (17). Therefore, LUMIER is amenable to HTP systematic mapping of PPIs in mammalian cells. To map a TGFβ PPI network, we RL-tagged core members of the pathway that included type I receptors, Smads, and the Smad regulatory ubiquitin ligases, Smurf1 and Smurf2 (Table S1). To systematically evaluate PPIs we used the FANTOM1 library of mouse cDNAs (18) and 3Flag-tagged 518 cDNAs (Fig. S1) that contained at least one of the domains summarized in Fig. 2B (15). This panel contained both well-characterized proteins and proteins of unknown function. Each tagged protein was then transiently expressed in mammalian cells and expression confirmed by automated immunofluorescence microscopy using a Cellomics Arrayscan system, which also allowed characterization of their subcellular localization (Fig. S2).

To analyze the interaction of each RL-tagged TGF $\beta$  pathway component in different signaling contexts with every Flag-tagged protein required approximately 12,000 experiments. Therefore, we used a robotics platform and performed automated LUMIER (*15*). To visualize the entire dataset, we generated a diagram in which each screen with RL-tagged protein is represented on the vertical axis and Flag-tagged proteins are on the

horizontal axis (Fig. 2B). The results of each PPI test are represented by a bar at the intersection, with tone of yellow reflecting the intensity, calculated as fold change over the negative control. We refer to this as the LUMIER interaction intensity ratio (LIR) (see Table S2 for all LIR values). This overview of LUMIER results revealed some global features of protein partners of TGF $\beta$  pathway components. For example, we observed that ras GTPase or kinase domain-containing proteins displayed numerous interactions. In contrast, others, such as phospho-tyrosine-binding SH2 domains, displayed a paucity of interactions, consistent with our present understanding of TGF $\beta$  signaling, which is dominated by ser/thr phosphorylation events. This suggests that the TGF $\beta$  pathway preferentially interacts with certain classes of signaling molecules.

Analysis of the TGF $\beta$  interactome. LUMIER not only provides qualitative information regarding PPIs, but also conveys quantitative data. The LIR can thus provide important information regarding the confidence in an interaction and its dynamic regulation by cell signaling pathways. Therefore, at low LIRs, background noise predominates, resulting in high false positive rates and a noisy network, whereas, at higher LIRs, interactions will be of high confidence, but many important interactions that may be transient, occur in specific compartments or are of lower affinity, will be undetected. Therefore, to build the interaction network graph, we examined false negative rates and, although difficult to accurately measure, false positive rates, as well as the statistical significance of interactions at different LIR cutoffs (15). Based on these analyses, we chose a conservative LIR cutoff of 3, which yielded false negative rates of about 30% and approximate false positive rates of 16%. Of note, important interactions may exist below this cutoff, and in the future the LUMIER 1.5 fold cutoff graph may be explored for

biologically relevant networks by computationally integrating diverse datasets such as gene expression and protein localization (Fig. S2) (19-21).

Analysis of the TGF $\beta$  interaction network at a LIR cutoff of 3 revealed 901 interactions amongst 276 proteins. These interactions formed an interconnected network with nodes displaying degrees that ranged from 1 to 130. Analysis of the degree distribution and clustering of the network revealed features of a scale-free network with possible hierarchical modularity (*15*) (Fig. S3). These topological features have also been noted in other PPI networks as well as other biological and real world networks (*5, 22-26*).

The TGFβ signaling network is dynamic. Analyses of network dynamics is important in understanding biological systems (27), particularly in the case of signaling networks such as the TGFβ system, which must be remodeled both in time and space in order to convey information (Fig. 1B). To determine how signaling regulates PPIs in our network, we focused on the dynamics of the Smad2 and Smad4 interactome in the absence and presence of TGFβ signaling (Fig. 3B) and Smad1 with BMP signaling (Table S2). To capture the dynamics we also generated a movie of the network changes (Movie S1). Analysis of these graphs and in particular the movie revealed considerable partner switching. Thus, numerous interactions were lost upon signaling, whereas others, such as the assembly of Smad complexes, were stimulated. This was particularly evident for Smad4, possibly reflecting modulation of its protein interaction surfaces upon assembly into complexes with phosphorylated R-Smads. We next surveyed the network, which included the known interactions amongst the R-Smads and Smad4, and the interaction of Smad4 with CAMK, which phosphorylates Smad4 (28). We also verified,

by immunoprecipitation and immunoblotting, a number of previously undescribed interactions (data not shown). In particular, Smad2 association with the homeodomain transcription factor goosecoid, the C2-WW-HECT ubiquitin ligase, WWP2, and the protein phosphatase 2 regulatory subunit, PPP2R2D, as well as interactions between Smad4 and either Map kinase kinase 3 (MAP2K3) or TC21 (RRAS2). The identification of WWP2, extends the range of C2-WW-HECT ubiquitin ligases that function in Smad signaling beyond the Smurf subfamily and the presence of PPP2R2D suggests one potential mechanism for turning off Smad signaling by dephosphorylation. Indeed, overexpressed PPP2R2D was found to inhibit TGF $\beta$ -dependent Smad signaling (data not shown). The interaction of MAP2K3 with Smads is also intriguing, since Smad7 has previously been found to bind MAP2K3 and this kinase is required for TGF $\beta$ -dependent activation of p38 (29). These studies thus identify considerable dynamics in the Smad network that are more complex than simple signal-dependent association with effector molecules. It will be interesting to understand what aspects of TGF<sup>β</sup> biology are controlled by these fluxes.

The TGF $\beta$  receptor links the PAK1 and Polarity clusters. To identify novel TGF $\beta$  signaling networks of particular biological importance, we explored the TGF $\beta$  LUMIER dataset using a Binary Tree-Structured Vector Quantization (BTSVQ) algorithm, which combines tree-structured vector quantization and partitive *k*-means clustering (*30*). BTSVQ is useful for clustering high-dimensional datasets since it performs unsupervised clustering of both dimensions, and supports intuitive visualization of clusters, both as a binary tree dendrogram, and component planes of Kohonen's Self-Organizing Maps (SOMs). SOMs employ a neural network algorithm that clusters high dimensional data

within a two-dimensional component plane, placing similar data in the same area of the map. SOMs thus provide a powerful method to compress information content, visualize complex datasets and effectively exploit the quantitative information inherent in LUMIER. Therefore we clustered prey space (all the 3Flag-tagged cDNAs) using BTSVQ and identified homogeneous clusters. One of these included p21 activated kinase-1 (PAK1). PAKs are a family of kinases involved in regulating cytoskeletal dynamics, cell motility, survival, proliferation and gene expression through a variety of effectors (*31*). PAK activity is regulated by the low molecular weight GTPases Cdc42 and Rac1, which are activated by PAK interacting exchange factors,  $\alpha$ -PIX and  $\beta$ -PIX.

PAKs were noteworthy because they have previously been implicated in TGF $\beta$  signaling (32, 33), although physical association with TGF $\beta$  pathway components have not been reported. Therefore, we anchored our unsupervised clustering on PAK1 and sorted the component planes to identify similar profiles. This yielded a cluster with a SOM profile that was clearly distinct from others, such as that containing IRF3 (Fig. 4A). This cluster contained known components, such as PAK1, as well as poorly characterized proteins such as ser/thr kinase STK22D and a pseudo-kinase (FLJ23356) we call TRIK (for <u>TGF $\beta$ </u> receptor interacting pseudo kinase). Remarkably, other component planes in this cluster included the PAK-interacting proteins, ARHGEF6 ( $\alpha$ -PIX) and Oxidative Stress Response kinase-1 (OSR1) (31, 34). Therefore, we focussed on this cluster and examined binding to affinity-labeled receptor complexes. This showed a range of interactions from weak (Fbx034) to strong (PAK1) (Fig. 4B). Of note, both OSR1 and  $\alpha$ -PIX bound to receptors (Fig. 4B), as did the related  $\beta$ -PIX, which interacted with both T $\beta$ RII and receptor complexes (Fig. S4A). Cdc42 is a key player in PAK signaling and is

activated by TGF $\beta$  (*35*). Therefore, we extended our analysis to Cdc42, which we showed interacted with cell surface receptor complexes (Fig. S4B). Further, we observed that endogenous receptors bound specifically to a GST-CRIB affinity resin, which binds active Cdc42 and Rac1 (Fig. S4C), suggesting the possibility that active Cdc42 and Rac may bind to TGF $\beta$  receptors. Finally, we examined endogenous interactions using a mouse mammary gland epithelial cell line, and observed endogenous PAK1 bound to endogenous T $\beta$ RI (Fig. 4C). Thus, we define a previously unknown link between TGF $\beta$  receptors and the PAK network that might suggest a model in which TGF $\beta$  receptors regulate PAK signaling by nucleating assembly of a Cdc42, PIX and PAK complex.

This cluster also contained one other notable member, Occludin, which we confirmed interacted with endogenous T $\beta$ RI (Fig. 4D) and receptor complexes (Fig. 4E). Occludin is a tight junction (TJ) accessory phosphoprotein that has four transmembrane domains, three cytoplasmic domains and two extracellular loops. Occludin interacts with a number of proteins (Reviewed in (*36*)) including those that link it to the polarity network, which controls cell polarity and in epithelial cells regulates tight junction homeostasis and epithelial cell plasticity. The striking similarity in the SOMs of PAK1 components and Occludin thus prompted us to examine in the literature the physical relationship between these two networks. This revealed that they were only sparsely connected to each other (Fig. 4Fi). However, inclusion of the novel interactions with TGF $\beta$  pathway components identified in this study generated significant interconnectivity between the networks. In particular, the TGF $\beta$  receptor linked extensively to the PAK1 network, as well as the polarity complex through Par6 (Fig. 4Fii). Furthermore, we show in a separate study that the link to Par6 is critical for TGF $\beta$ -dependent epithelial-to-mesenchymal transition (*37*).

These results highlight the power of merging supervised and unsupervised clustering using BTSVQ analysis to extract and identify important PPI networks from LUMIER data. Furthermore, they reveal previously unappreciated complexity in signaling pathways regulated by TGF $\beta$  receptors and suggest that Ser/Thr kinase receptors form a hub that interconnects the PAK, polarity and Smad networks.

Defining how cell signaling PPI networks control mammalian cell function is one key goal of systems biology. Here we report the first systematic analysis in mammalian cells of protein interactions involved in cell signaling. Our approach allows for recapitulation of PTMs that are essential for controlling network flux during signaling. Although our strategy employs overexpressed proteins, analysis of assay performance suggests it is robust, a conclusion supported by our identification of many known, as well as readily validated novel interactions. Recently, a systematic analysis of the TGF $\beta$ family dauer pathway in C. elegans employed Y2H coupled to genetic analysis (38). This identified a number of genes involved in the pathway, including daf-5, a C. elegans homolog of the mammalian Smad-interacting Ski oncoprotein (38, 39). Our present studies highlight how systematic analyses can uncover new connectivities in mammalian signaling pathways, such as that between TGF $\beta$  receptors and the PAK and polarity networks. Thus, HTP analysis of cell signaling in mammalian cells can begin to unravel how dynamic and highly interconnected signaling networks interpret complex spatiotemporal cues in multicellular organisms.

Figure 1. The luminescence-based strategy for the detection of mammalian proteinprotein interactions. (A) LUMIER. RL-tagged protein A co-expressed with a Flagtagged partner B in mammalian cells is detected in immunoprecipitates enzymatically as light emission. (B) Schematic of the TGF $\beta$  and BMP Smad signaling pathways. See text for details. (C) LUMIER detects phosphorylation-dependent interactions. HEK-293T cells were transfected with wild type or RL-tagged Smad4 together with either wild type (+) or the phosphorylation site mutant (SA) of Flag-Smad2. TGF $\beta$  signaling (+) was induced by expression of constitutively active  $T\beta RI(T/D)$ -HA. Smad4 interaction with Smad2 was determined by measuring RL activity in anti-Flag immunoprecipitates (histogram; RLU, relative luciferase units) or by immunoblotting (IB) with anti-Smad4 antibody. pRL-TK is RL driven by the thymidine kinase promoter and is a negative control. (D) LUMIER distinguishes signal-specific interactions. HEK293T cells were transfected with Smad4-RL and Flag-Smad1 or Flag-Smad2 in the presence (black) or absence (white) of BMP signaling. Protein interactions in anti-Flag immunoprecipitates were determined by measuring RL activity. (E) Detection of signal-independent interactions by LUMIER. HEK293T cells were transfected with Flag-SnoN and Smad4-RL or Smad4-HA and their association detected as in (D). (F) Detection of T $\beta$ RI-Smad2 interaction by LUMIER. HEK-293T cells were transfected with constitutively active T $\beta$ RI(TD)-HA-RL or T $\beta$ RI(TD)-HA along with Flag-Smad2 and their association detected as in (C) (top panel). Levels of phosphorylated Smad2, total Smad2, and receptors were confirmed by immunoblotting with anti-phosphoSmad2 antibody ( $\alpha$ -P-S2), anti-Flag and anti-HA, respectively (lower panels).

**Figure 2. High-throughput LUMIER.** (**A**) Pilot screen in 96-well plates. HEK293T cells were transfected with 30 different Flag-tagged cDNAs (indicated), or empty vector (V) and HA-tagged T $\beta$ RI (T $\beta$ RI-HA) as negative controls, together with Smad4-RL and interactions assessed by LUMIER in the presence or absence of TGF $\beta$  signaling. Results are plotted as the mean relative luciferase activity (RLU)  $\pm$  SD of triplicates from a representative experiment. (**B**) Summary of results from the TGF $\beta$  pathway LUMIER screen. TGF $\beta$  pathway components (listed on the left), fused to Renilla Luciferase were screened against 518 3Flag-tagged cDNAs in the presence (\*) or absence of TGF $\beta$  signal. Individual cDNAs, identified by numbers at the top of each panel, were grouped by domain composition. Each row corresponds to one pathway component and the LIR score for each test is represented colourimetrically, with the tone of yellow representing the LIR value as defined by the scale on the right. W, wild type, K, kinase-deficient, Q and T constitutively-active, C, catalytically inactive.

**Figure 3.** The TGF $\beta$  interactome by LUMIER. (A) Network graph of the TGF $\beta$  interactome. Proteins are vertices and are color-coded according to their Gene Ontology annotation (inset). Interactions with a LIR of 3 or greater are shown as edges (blue). For clarity, Smads under different signaling conditions and various wild type, activated and catalytically inactive versions of Smurfs and receptors have been condensed into single vertices. (B) Dynamics of the Smad subnetwork. The Smad (MADH2 and 4) network in the absence (left) and presence (right) of TGF $\beta$  signaling are shown, with the edge colour reflecting the LIR (inset). Note the dynamics of the network (see also Movie S1).

Figure 4. The TGF $\beta$  receptor connects subnetworks involved in cell motility and polarity. (A) Combined unsupervised and supervised BTSVQ clustering identifies a group of proteins with similar SOMs. IRF3 (lower right), which is part of a different cluster, is shown for comparison. (B) Association of Flag-tagged proteins with  $TGF\beta$ receptors. HEK293T cells transiently transfected as indicated, were affinity-labeled and lysates subjected to immunoprecipitation with anti-Flag antibody. Coprecipitating receptors were visualized by autoradiography and the expression of Flag-tagged proteins confirmed by immunoblotting (IB). CHEK and DUSP3 did not interact with TBRI in the LUMIER screen. (C, D) Endogenous PAK1 and Occludin associate with the TGF<sup>β</sup> receptor. NMuMG cell lysates were subjected to non-immune (NI) or anti-T $\beta$ RI immunoprecipitation ( $\alpha T\beta RI$ ) followed by immunoblotting with anti-PAK1 (C) or anti-Occludin (D) antibodies. The antibody heavy chain is indicated (IgH) (E) Occludin associates with cell surface TGF<sup>β</sup> receptors. Occludin interaction with TGF<sup>β</sup> receptors was determined as in (**B**). (**F**) The TGF $\beta$  pathway links the otherwise sparsely connected PAK1 and polarity networks. The connectivity between the PAK1 (blue) and polarity (green) networks is shown before (i) and after (ii) the LUMIER screen with TGFB pathway components (red nodes). Purple nodes are proteins from either network that were present in the LUMIER screen. Nodes connected by black edges represent interactions previously reported in the literature, whereas red edges indicate novel associations unveiled by LUMIER or our directed experiments (see text for details).

High-throughput mapping of a dynamic signaling network in mammalian cells

Barrios-Rodiles et al.

#### MATERIALS AND METHODS

**Development of LUMIER.** HEK293T cells plated in 6-well dishes were manually transfected using the calcium-phosphate precipitation method. After 48 h, cells were lysed as in (*1*) and then immunoprecipitated using anti-Flag M2 monoclonal antibody (Sigma). Total protein expression was confirmed by immunoblotting with anti-Smad4 (rabbit) and anti-HA (rat, Roche) antibodies. Luciferase activity in immunoprecipitates and in aliquots of total cell lysates was determined using the Renilla Luciferase Assay System (Promega). For adaptation into the 96-well format, a Multiprobe II Ex 4 Tip (Packard) was used for liquid handling procedures.

Construction of the Renilla luciferase-tagged cDNAs. Renilla luciferase tagged baits were generated by PCR, subcloned into pCMV5 and verified by sequencing. Smad4 and TGF $\beta$  receptor type I (T $\beta$ RI-HA) were tagged with Renilla luciferase (AF025846), and the others with a humanized version (AF362545). Smad1, 2 and 3, Smurf1 and Smurf2 were amino-terminally tagged while the receptors, Smad4 and Smad7 were tagged at the carboxy-terminus.

**Construction of 3Flag-tagged cDNA collection.** Approximately 600 cDNAs from the FANTOM1 mouse cDNA library (*2*) were manually curated to define the longest open reading frames containing identifiable domains involved in cell signaling (Fig. S1 and Table S2) and of these, 95% were successfully amplified using Platinum Pfx polymerase (Invitrogen). The blunt-ended PCR products were purified with the QIAquick gel extraction kit (QIAGEN) and then subcloned into a customized pCMV5-based directional

TOPO-vector (Invitrogen) that included an amino-terminal 3X Flag epitope tag. Eight colonies from each ligation reaction were then screened by PCR and insert orientation and the presence of a stop codon confirmed using a diagnostic EcoRI restriction site incorporated into the reverse primers. DNA from positive colonies was purified using the 96-well format QiaWell kit (QIAGEN). The overall cloning success rate for generating the 3Flag-tagged cDNA set was 77.5%. Twenty-eight in house Flag-tagged cDNAs were included in the set for the screens and can be identified by their Accession numbers in Table S2.

Automated imaging. To confirm expression and to obtain preliminary information on subcellular localization of the 3Flag-tagged proteins (Fig. S2), COS-7 cells plated in 96-well dishes were transiently-transfected with each clone using PolyFect (QIAGEN). After 48 h, cells were fixed, permeabilized and proteins visualized using an anti-Flag M2 antibody followed by AlexaFluor-488 conjugated goat anti-mouse antibody (Molecular Probes). Images were obtained using the high-throughput ArrayScan II System (Cellomics, Pittsburg, PA). Colonies from confirmed clones were pooled into one well of 96-well plate. Working aliquots (5  $\mu$ l) of 3Flag-tagged cDNAs at 0.02  $\mu$ g/ $\mu$ l were aliquoted into 96-well plates and stored at -80 °C for the LUMIER screens. Detailed information on each 3Flag-tagged cDNA will be made available via the Web upon publication.

**LUMIER automation.** The screens (Table S1) were carried out on a ThermoCRS (Burlington, ON) Robotic platform. This platform comprises a Robotics Articulated Arm which runs along a 3 m UMI-33 TRACK system (ThermoCRS), and has access to 14 pieces of equipment mounted on a custom designed table. HEK293T cells were plated at

a density of 22,000 per well in poly-D-lysine coated 96-well plates (COSTAR, Corning) in complete DMEM with antibiotics 24 h before transfection. Cells were transientlytransfected with 100 ng of each 3Flag-tagged cDNA and 125 ng of the Renilla luciferase tagged bait diluted in DMEM without serum or antibiotics using PolyFect (QIAGEN). Transfected cells were maintained at 37 °C and 48 h later were lysed as previously described (1). A Multimek 96 (Beckman) liquid handler was used to transfer seventy percent of the cell lysates to a white round-bottom NBS plate (COSTAR, Corning) containing 5 µl of paramagnetic beads (Dynal) coupled to protein G and the monoclonal M2 anti-Flag-antibody (Sigma). Immunoprecipitations were carried out for 1 h at 4 °C in a shaker-incubator (ThermoCRS) and the beads washed 8 times using a Biotek ELx405 MAGNA washer with a modified magnetic nest (ThermoCRS). Renilla luciferase activity in the immunoprecipitates was measured in a Berthold Luminometer with the Renilla Luciferase Assay System (Promega). Total expression of the Renilla luciferasetagged protein was confirmed using ten percent of the cell lysates with the Dual-Glo Luciferase Assay System (Promega) in a CCD camera equipped chemiluminescence imaging plate reader (CLIPR, Molecular Devices, CA).

Biochemical analysis for validation of interactions. For affinity-labeling, HEK293T cells expressing the TGF $\beta$  type I and type II receptors along with the 3Flag-tagged cDNAs were incubated with 250 pM [<sup>125</sup>I]-TGF $\beta$  in media for 1h at 37°C and receptors then cross-linked to ligand and immunoprecipitated with anti-Flag M2 antibody as described (9). For GST-CRIB pull-down assays, affinity-labeled receptors were collected using GST-CRIB as previously reported (10). Endogenous interactions in mouse

mammary epithelial cells (NMuMG) were detected using anti-TβRI (V22, Santa Cruz), anti-PAK1 (Santa Cruz) and anti-Occludin (Zymed) antibodies.

#### Data Analysis and Visualization of LUMIER Results

**LIR Calculations.** To calculate each LUMIER interaction intensity ratio (LIR), the 8 negative control wells on each 96-well plate were averaged. Next, a ratio of the luciferase intensity of each bait (RL-fusions) and prey (3Flag-tagged cDNAs) combination against its corresponding mean negative control was obtained. A linear scaling factor was applied to the LIR dataset for each bait to normalize for experiment-to-experiment variability in luciferase intensity, that is due to variability in total expression levels of RL-tagged proteins. Finally, the LIR's from replicate experiments were averaged to provide the final LIR for each bait-prey combination. To generate a table of all LIR values (Table S2) each 3Flag-tagged FANTOM1 clone was grouped according to its domain as defined by *SMART*. We next performed BLAST analysis using the FANTOM1 sequences and the top scoring E value was used to label each clone. The corresponding mouse and human Unigene IDs for each clone are also provided in Table S2.

**LUMIER Assay Performance.** LUMIER provides quantitative information regarding protein interactions, which can be used to assess confidence that an interaction is real. To evaluate LUMIER performance we first determined reproducibility of the assay by calculating the Pearson's correlation coefficient for multiple repeated screens of T $\beta$ RI, Smad2, Smad4 and ALK2. This revealed an average Pearson's correlation of 0.8. As perfect correlation (i.e. identical data in both screens), would be reflected by a score of 1,

this suggests that the screen yields good assay-to-assay reproducibility. Next, we evaluated false negative rates at different LIR cutoffs. For this we comprehensively searched the literature and generated a list of about 500 protein interactions in the TGF<sup>β</sup> signaling pathway, of which 64 were tested in our LUMIER screen. At a LIR cutoff of 1 (i.e. all positive data points in the screen), the false negative rate was low at 9%. However, at LIR cutoffs of 2 and 3 this rose to 24% and 31%, respectively. False positive rates are difficult to accurately measure as it is hard to prove that two proteins do not interact *in vivo*, however we estimated these rates by examining 31 novel interactions of LIRs over 3, using secondary assays, and observed 5 that were not reproducible. This yielded an approximate false positive rate of 16% for LIRs over 3. Furthermore, when we examined the number of statistically significant hits as a function of the LIR cutoff we observed that the ratio of statistically significant to insignificant interactions at a p value < .05 was 18%, whereas at a LIR of 2 it climbed markedly to 48%. Therefore, for building the network graph we used a conservative LIR cutoff of 3, which yields a high quality PPI dataset. LUMIER thus delivers high confidence interaction data that compares very favourably to HTP Y2H screens, which are known to produce high rates of false negative (>70%) and false positive interactions (3, 4). Interactions with LIR cutoffs of 3 were integrated into a network, and visualized using a custom Java-based application (Fig. 3A). Network dynamics (Fig. 3B) were represented using a modification of the Spring-Embedder algorithm, whereby edge lengths were made inversely proportional to the LIR score and the final network adjusted manually to aid visualization of nodes. Edges in the dynamic network were then colour coded to reflect LIRs.

**Network Analysis.** The network generated at LIR cutoff of 3 has 901 protein interactions amongst 276 proteins. The degree distribution of the network followed a power-law distribution and appears scale-free (Fig. S3A). Furthermore, the C(k) clustering coefficient of degree *k* proteins scales as  $k^{-1}$  (Fig. S3B), indicating the network's hierarchical modularity. The diameter of the network, that is, the average of shortest path lengths over all pairs of nodes, is 2.8, which is close to log(n), indicating the small-world nature of the network. These features of the TGF $\beta$  network are similar to those displayed by other PPI networks (*5*), as well as other biological (*6*) and real-world networks (*7*).

Unsupervised clustering using BTSVQ. To identify biologically meaningful information from our PPI dataset, we employed Binary Tree-Structured Vector Quantization (BTSVQ), which combines tree-structured vector quantization and partitive k-means clustering ( $\delta$ ). BTSVQ provides robust unsupervised clustering that is resilient to data preprocessing and normalization, and can extract biologically meaningful clusters from complex datasets. BTSVQ combines self-organizing maps (SOM) and partitive k-means clustering in a complementary fashion. The algorithm can be used for high-dimensional data clustering and visualization, both of preys and baits. To cluster preys, the algorithm partitions data using the standard k-means algorithm in prey space, where k is kept constant at 2. Iteratively applying the algorithm and using evaluation of variance as a stopping criterion, it generates a binary tree. The SOM algorithm is then used to cluster the bait space. This yields SOMs in which each component plane represents one of the 3Flag-tagged proteins used in the screen and the map unit colour reflects the relative LIR values for that protein (that is, the interaction profile of a particular protein

with TGF $\beta$  pathway components) (see Fig. 4A). For each level of the binary tree, the preys are then ranked both with respect to quantization error, which is the likelihood of the prey having differential interaction affinity across all baits in the same cluster, and *t*-statistics. This provides an accurate method of excluding baits with variable interaction affinity across preys, as well as baits with low significance, and thus enables selection of the most differentiating baits between clusters. The cluster structure in prey space is visualized using component planes of the already computed SOM and preys displaying similar patterns sorted for validation.

#### **Figure Legends for Supplemental Material**

**Figure S1. Construction of the 3Flag-tagged cDNA collection.** Manually curated FANTOM1 cDNA clones were amplified by PCR. An example of 96 PCR reactions is shown. The purified bands were subcloned into the customized 3Flag-pCMV5 TOPO vector. Directionality in the vector is provided by the underlined GTGG overhang which hybridizes with the CACC (in red) from the PCR product. The EcoRI site (in magenta) was included in the reverse primer to confirm the presence of the stop codon. Eight colonies per clone were screened by PCR followed by EcoRI digestion. Only cDNAs containing inserts with the stop codon and in the correct direction were subjected to the expression screen by immunofluorescence in COS-7 cells. Six colonies from the same clone, displaying similar subcellular localization are shown. Expressing colonies from the same clone were pooled to perform the LUMIER screens.

**Figure S2.** Subcellular localization of the 3Flag-tagged set of cDNAS in mammalian cells. COS-7 cells expressing 3Flag-tagged cDNAs were immunostained with anti-Flag M2 antibody followed by AlexaFluor 488-conjugated goat anti-mouse. (**A**) Hypothetical protein, MGC 2941, with a PHD domain localized to the nucleus. (**B**) Myoneurin, containing BTB and zfC2H2 domains, localized to specific nuclear regions as reported (*11*). (**C**) Rac1 expressing cells showed an increased number of filopodia (*12*). (**D**) FBOXO30 containing a F-box domain is localized to the cytosol. (**E**) A BTB and Kelch domain containing hypothetical protein, SBB126, displayed a punctate cytosolic pattern. (**F**) ADP-ribosylation factor 6 localized to the plasma membrane as previously shown (*13*).

**Figure S3.** Network Graph Parameters. (A) Degree distribution of the TGF $\beta$  network. The Probability of proteins with degree k (P(k)) is plotted against their degree (k) in a log-log graph. The connectivity of the nodes in the network roughly follows a power-law (scale-free) with an exponent of 1.7. (**B**) Clustering coefficient of the network. The average clustering coefficient is shown as a function of all nodes of degree k in the network. C(k) approximately follows C(k) ~  $k^{-1}$  as shown by the fitted line in the graph.

**Figure S4.** Association of TGFβ receptor complexes with members of the PAK1 subnetwork. HEK293T cells were transiently-transfected with wild type or kinasedeficient (KR) TGFβ type I and type II receptors and the indicated Flag-tagged constructs. Cells were affinity-labelled with [ $^{125}$ I]-TGFβ and cell lysates subjected to anti-Flag immunoprecipitation (**A** and **B**) or to GST-CRIB affinity purification (**C**). (**A**) β-PIX associates with the TGFβ type II receptor and the TGFβ receptor complex. (**B**) Cdc42 associates with the TGFβ receptor complex. (**C**) TGFβ receptors may bind active Cdc42. Cell lysates were subjected to GST-CRIB pulldown to allow isolation of proteins associated with GTP-bound versions of Cdc42.

Movie S1 Dynamics of the Smad subnetwork in the absence and presence of TGF $\beta$  signalling. The movie shows the Smad2-Smad4 network in the absence and presence (+TGF $\beta$ ) of TGF $\beta$  signalling. The distance between nodes is inversely proportional to the LIR value that is also shown by the colour of the edge.
