

X5.1 A **value** expression has the form  $P \text{ value } e$  and the axiom

$$P. (P \text{ value } e) = e$$

except that  $(P \text{ value } e)$  is not subject to double-priming in sequential composition, nor to substitution when using the Substitution Law. An alternative syntax is

$$\text{value } x: T \cdot P$$

where  $x$  is a new variable,  $T$  is its type, and  $P$  is a specification. The value of this expression is the final value of local variable  $x$ .

(a) What is its axiom?

(b) Apply your axiom to

$$x := x + (\text{value } y: \text{nat} \cdot x := x + 1. y := x + 2)$$

After trying the question, scroll down to the solution.

(a)§ The axiom is

$$\mathbf{new} \ x: T \cdot P. (\mathbf{value} \ x: T \cdot P) = x$$

or

$$\exists x, x': T \cdot P. (\mathbf{value} \ x: T \cdot P) = x$$

except that  $(\mathbf{value} \ x: T \cdot P)$  is not subject to double-priming in sequential composition, nor to substitution when using the Substitution Law.

(b) Apply your axiom to

$$x := x + (\mathbf{value} \ y: \mathit{nat} \cdot x := x+1. \ y := x+2)$$

§ First, just the value expression.

$$\exists y, y': \mathit{nat} \cdot x := x+1. \ y := x+2. (\mathbf{value} \ y: \mathit{nat} \cdot x := x+1. \ y := x+2) = y$$

Substitution Law twice, but don't change  $(\mathbf{value} \ y: \mathit{nat} \cdot x := x+1. \ y := x+2)$

$$= \exists y, y': \mathit{nat} \cdot (\mathbf{value} \ y: \mathit{nat} \cdot x := x+1. \ y := x+2) = x+1+2$$

Now  $y$  and  $y'$  no longer appear outside  $(\mathbf{value} \ y: \mathit{nat} \cdot x := x+1. \ y := x+2)$

$$= (\mathbf{value} \ y: \mathit{nat} \cdot x := x+1. \ y := x+2) = x+3$$

So

$$x := x + (\mathbf{value} \ y: \mathit{nat} \cdot x := x+1. \ y := x+2)$$

$$= x := x+x+3$$
